

Functions in Python

UNDERSTANDING FUNCTIONS WITH EXAMPLES

What is a Function?

- ▶ A function is a block of organized, reusable code that performs a single, related action.
- ▶ Functions help in organizing the code and improving readability.
- ▶ They allow code to be called multiple times without repetition.

Syntax of a Function

- ▶ `def function_name(parameters):`
 `"docstring"`
 `statement(s)`
- ▶ `function_name`: Name of the function.
- ▶ `parameters`: Inputs to the function (optional).
- ▶ `docstring`: Describes the function's purpose (optional).
- ▶ `statement(s)`: The block of code that runs when the function is called.

Example of a Simple Function

- ▶ `def greet():`
 `"""This function greets the user."""`
 `print('Hello, World!')`
- ▶ Here, 'greet' is the function name.
- ▶ It prints a message when called.

Calling a Function

- ▶ Once defined, you can call a function using its name:
- ▶ `greet()`
- ▶ Output:
Hello, World!

Function with Parameters

- ▶ `def greet(name):`
 `"""This function greets a person by name."""`
 `print(f'Hello, {name}!')`
- ▶ 'name' is the parameter passed to the function.
- ▶ The function prints a personalized greeting based on the input.

Calling a Function with Parameters

- ▶ `greet('Alice')`

- ▶ • Output:

Hello, Alice!

- ▶ You can call the function with different names to greet other people.

Return Statement in Functions

- ▶ Functions can return a value using the 'return' statement.
- ▶

```
def add(a, b):  
    """This function returns the sum of two numbers."""  
    return a + b
```

Example of a Function with Return

- ▶ `sum = add(5, 3)`
`print(sum)`

- ▶ Output:
8

- ▶ The 'add' function returns the sum of 5 and 3.

Conclusion

- ▶ Functions are a fundamental part of Python programming.
- ▶ They help to make code reusable, modular, and easier to maintain.
- ▶ Use functions to break down your code into smaller, manageable parts.
